Malignant Catarrhal Fever in a Red Angus Cow

BY: LAUREN RICER
OVC 2015
History & Signalment

- Three year old Red Angus Cow
- Complaint: Blindness
- From 15 Red Angus Cow Herd
- Managed on Pasture
- Katahdin ewes and lambs housed in the barn on the farm property
**Initial Physical Exam**
- Temperature 39.8°C
- HR & RR: WNL
- Harsh lung sounds
- Significant bilateral corneal edema
- Nasal ulceration & foul discharge
- 5 months pregnant
• Corneal edema and nasal ulceration seen on initial physical exam
Differential Diagnosis

- Infectious Bovine Rhinotracheitis
  - Bovine Herpes Virus 1
- Bovine Viral Diarrhea
  - Bovine Viral Diarrhea Virus
- Malignant Catarrhal Fever
  - Ovine Herpes Virus 2
Initial Treatment & Follow up

- Oxytetracycline LA, 1mg/10kg BW SQ
- Free choice hay, grain and water
- Follow Up Visit
  - Temperature 39.6C
  - Respiratory noise had subsided, regular breathing pattern
  - Nasal ulceration resolved
  - Corneal edema persisted with episcleral & conjunctival hyperemia bilaterally
- Continued Oxytetracycline LA & added one dose of Predef (Isoflupredone) at 20mg/kg BW IM
One Week Later...

- Continual improvement in respiratory signs
- Absence of discharge or ulceration
- No improvement in regards to corneal edema, early signs of corneal ulceration
- At no time were there any coronary band or mucosal lesions detected
Laboratory Tests

- Whole blood (EDTA) was collected for PCR to detect OvHV-2 DNA and sent to Prairie Diagnostic Services Inc. Saskatoon, SK
- Serum was submitted for virus neutralization for IBR
- Whole blood (EDTA) was submitted for PCR to screen for BVD
- The IBR and BVD tests were run at AHL, Guelph ON
Final Examination

- Three weeks post initial exam
- Temperature 39.5°C
- RR was normal, however respiratory sounds had returned
- Corneal edema had progressed to granulation tissue centered on the eye and neovascularization of the cornea
- A slight menace was elicited however, vision was severely limited
- BCS decreased from 3/5 to 2/5
Results

- IBR and BVD: Negative
- MCF, OvHV-2: Positive
- The cow was humanely euthanized after the confirmation of MCF due to a guarded prognosis and non-improvement of ocular signs
- A necropsy was not performed
Discussion

- OvHV-2 can cause sheep associated Malignant Catarrhal Fever (SA-MCF)
  - Typically fatal to cattle and other ungulates
  - Transmission from direct or indirect contact with sheep
- Alcelaphine herpesvirus 1 (AIHV-1) causes the wildebeest-associated MCF (WA-MCF)
  - Causes outbreaks in cattle in Eastern and Southern Africa where wildebeest are found.
- The natural reservoir species (sheep and wildebeest) do not exhibit clinical signs
Clinical Signs

- This case described the “head and eye” form
  - High fever, anorexia, depression, profuse mucopurulent nasal discharge, dyspnea, stertor and diarrhea
- Ocular signs: exophthalmos, blindness, nystagmus, photophobia and lacrimation
- Pathognomonic for “head and eye” MCF is corneal edema
- Prognosis is correlated with ocular signs. A poorer prognosis was assigned to a case where the signs do not resolve or progress
Why was this case unique?

- This case was particularly interesting because SA-MCF is a sporadic and rare disease in Ontario.
- As well cattle typically are euthanized or die after 2-18 days after diagnosis, however this cow survived for 3 weeks.
- Current research has showed it is possible for a cow to recover and survive with a chronic form of the disease.
- Chronic lesions are often vascular and/or ocular.
Areas of Future Research

- Development of a vaccine to protect populations of cattle, farmed deer and bison at risk
  - MCF virus-specific sera have been used to identify important diagnostic or protective antigens to incorporate into a vaccine
  - Cattle surviving natural infection remained immune despite a lower titre of serum neutralising antibody than the test immunized cattle (Russell et al, 2009)
- Promising results using an intranasal challenge model and attenuated AIHV-1 vaccine producing a protective mucosal response (O’Toole & Li, 2014)
Recommendations

- Recommendations to this client were to discontinue feeding the refusal hay from the sheep to the cows to prevent another case of SA-MCF.
- Another method of transmission that could occur would be if the sheep manure was spread on the hay fields that were then harvested for cattle feed.
Summary

- SA-MCF can be fatal to cattle and other ungulates following direct or indirect contact with sheep.
- Mortality is high for confirmed cases of this disease, there is no treatment and either vascular or ocular signs will persist.
- Even though a case of MCF would be rare it should be considered a differential diagnosis when a cow presents with ocular and nasal lesions especially if sheep are present on the farm.
Acknowledgements

- Thank you to Dr. Ferguson from Napanee Veterinary Hospital for his assistance on this case and for helping me construct my report
- Thank you to all the veterinarians and staff at NVH for hosting my 4th year externship
- OABP for allowing me to present my case and for the Bovine Trust Education Stipend to help support my final year of veterinary school.
